

I/O in Linux Shell Lab

Summary: This lab introduced the basics of shell interaction by examining how Bash receives input and returns output or errors. I practiced generating text, performing simple calculations, and clearing the terminal to see how the shell processes different types of commands. The overall goal was to understand the fundamentals of interacting with Linux through the command line.

Commands Used:

Overview: In this lab, I worked with a few basic Bash commands to explore how the shell handles input and output. I used `echo` to print text back to the terminal, such as entering a phrase and having the shell return it. The argument that follows this command can be enclosed with quotation marks, but it is not required. Next, I used the `expr` command to perform simple calculations, which only work when each part of the expression is separated by spaces. After experimenting with these commands, the terminal became cluttered, so I used the `clear` command to reset the workspace.

Reflection: This lab strengthened my understanding of how the shell handles basic input and output. Using simple text and arithmetic examples made it easier to see how input is processed and how errors appear. The tasks were straightforward and helped me build confidence in navigating and communicating with the Linux command line.
