

Linux File Navigation Lab

Summary: In this lab, I worked in a Linux environment to practice navigating the file system and reviewing the contents of different files. My role was to move through various directories, locate specific reports, and analyze the information within certain files. The purpose of this lab is to build foundational skills for locating and interpreting file data through the command line.

Commands Used:

```
pwd  
ls  
cd  
cat  
head
```

Overview: The activity began with identifying my current location in the file system using `pwd`, which prints the full path of the current working directory. From there, I used `ls` to view the files and folders available to me and get a sense of the structure I was working in. To navigate further into the environment, I used the `cd` command, which allowed me to move into the reports and users directories to explore the information stored there.

Once inside these directories, I relied on `ls` again to confirm which files were present before opening specific reports. I used `cat` to display the full contents of a user report, which made it easy to review details like usernames, departments, and employee IDs. After finishing with the reports, I moved into the logs directory to examine system activity. Instead of printing the entire log file, I used `head` to view the first ten lines of the file, which provided a quick preview of the warnings and events recorded there.

Together, these commands helped me move through the file structure, locate required files, and extract the information needed to answer the lab questions. The workflow highlighted how navigation and file-viewing tools work together when analyzing data through the shell.

Reflection: Knowing how to navigate between directories and read the files within them is an essential task for security professionals. This lab gave me practical experience moving through a Linux environment and pulling information directly from system files. It also helped reinforce how different commands work together when locating reports or reviewing log data. Overall, it strengthened my familiarity with working in the shell and interpreting information without relying on a graphical interface.
