

File and Directory Management Lab

Summary: This lab focuses on reorganizing directories by creating new folders, removing outdated items, and relocating files to their proper locations. I was responsible for readjusting the structure, cleaning up unnecessary files, and documenting the changes. These tasks demonstrate how basic file management commands support maintaining an organized and functional Linux environment.

Commands Used:

```
mkdir
rmdir
mv
rm
touch
nano
```

Overview: To start reorganizing the existing directory for future use, I created a new subdirectory using the `mkdir` command. This new directory provided an additional location for storing relevant information. After confirming the change, I removed an outdated directory with `rmdir` to clean up the workspace and eliminate folders that were no longer needed. These initial steps helped establish a clearer layout before adjusting the remaining contents.

Next, I focused on restructuring the files within the existing directories. I used the `mv` command to relocate a file into the appropriate folder so that similar items were grouped together. Once I verified that the file was moved, I deleted any unnecessary files with `rm` to remove outdated or temporary content. Throughout this process, I used `ls` to confirm that each directory reflected the expected structure and that only the applicable files remained.

To complete the reorganization, I created a new text file using the `touch` command and opened it in the `nano` text editor to document the updates made during the activity. Inside `nano`, I added a brief note describing the completed tasks and saved the file before returning to the shell. I then cleared the terminal and displayed the file's contents to confirm that the information had been recorded correctly. These steps illustrate how directory management, file manipulation, and basic text editing work together to maintain a tidy and efficient Linux setup.

Reflection: This activity highlighted how essential basic file management commands are for keeping a Linux environment organized and easy to navigate. Creating, moving, and removing files and directories helped reinforce how each command contributes to maintaining a clean structure. Editing the final tasks file in `nano` also provided useful practice with making quick text updates directly from the terminal. Altogether, the steps demonstrated how small adjustments can make a directory far more structured and manageable.
